

Diana's Delightful Issue Tracker

Overview

Welcome to my cozy little code project - a web-based Issue Tracker that I stitched together using Flask, JavaScript, and a sprinkle of CSS. It's designed to help track problems, tasks, or bugs in a tidy and interactive way. It's small, simple, but mighty when it comes to practicing real-world CRUD operations.

Why I Made This

This wasn't just about making something useful (though it is!). It was about stretching my skills - blending backend logic with frontend interactivity, and making the experience seamless. The goal was to build something full-stack that felt alive: reactive, clean, and easy to expand upon.

How It Works

- You fill out a form to report an issue - Title, Description, Priority.
 - Flask takes that input and saves it to a SQLite database.
 - JavaScript then fetches all current issues and dynamically displays them right on the page - no reload needed.
 - You can delete or edit entries, and everything updates in real-time.
- It's smooth, satisfying, and surprisingly addictive to click around in.

Tech Stack Breakdown

- Flask: Manages routing and backend logic
- SQLite: Handles data storage locally
- JavaScript: Fetches and dynamically renders data
- HTML/CSS: The layout, style, and interactions

What I'd Love to Add Next

- A login system so users have their own issue boards
- Time tracking to see when an issue was submitted or last updated
- Status filters (e.g., Open, In Progress, Resolved)
- A hosted version live on Render or GitHub Pages

Final Thoughts

This project reminded me why I enjoy building things from scratch - there's something satisfying about seeing data flow between client and server, about clicking a button and watching the UI respond instantly. It's not just

Diana's Delightful Issue Tracker

code, it's a conversation between parts, and I'm proud of how this one turned out.
